

Cryptography - Lab 7 - MAC and SSL/TLS Handshake

Javier Antxon Garrues Apecechea

Student ID: 24647808

In this lab we will get familiar with one-way hash functions.

Part One: Message Authentication Code (MAC)

2. GENERATING HMAC USING KEYS

2.1 Practice HMAC:

Without using a file:

```
javiergarru — zsh — 100x5
[(base) javiergarru@MBP-de-Javier-2 ~ % echo -n "test" | openssl dgst -md5 -hmac 1234567890abcdef
(stdin)= d0c9f08ff36829370489c2ddef5e419f
(base) javiergarru@MBP-de-Javier-2 ~ % ]
```

Finding hmac of a file:

```
javiergarru — zsh — 100x5
[(base) javiergarru@MBP-de-Javier-2 ~ % echo -n "test" > test
[(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -md5 -hmac 123456789abcdef test
HMAC-MD5(test)= 9405a27116f94ffb2c1be1f01f593531
(base) javiergarru@MBP-de-Javier-2 ~ % ]
```

Question: Compared to hash functions, why MAC can resist man-in-the middle attack?

Because it uses a key that is shared by sender and receiver. The adversary doesn't have access to that key. On the other hand, using Hash the adversary can position himself in the middle and generate the same hash as any of the participants of the communication.

Question: Suppose we have a MAC function with c binary digits MAC code and k binary digits key, what are the levels of effort of the brute-force attacks on the MAC code and the key? What is the best strategy of attackers?

The levels of effort of the brute-force attack on the MAC code is $O(c)$ and the levels of effort of the brute force attack on the key is $O(k)$. The best, and theoretically only, strategy attackers can follow is to try all the possible combinations of key (2^k) and possible plain texts and generate the HMAC of those combinations until finding one that matches the HMAC. In conclusion, the best strategy is brute-force attack. Although the size of c can be smaller than k , the fact that the Hash functions aren't invertible makes impossible going from the 2^c -size space to the plain-text one. Some other strategies of attacking HMAC are here mentioned (but they are mostly based on implementation design mistakes):<https://crypto.stackexchange.com/questions/95568/is-there-any-good-attack-model-of-hmac>.

2.2 Practice HMAC on files with different sizes

Create a large file and find the hmac:

```
javiergarru@MBP-de-Javier-2 ~ % head -c 5000000000 /dev/urandom > xfile
javiergarru@MBP-de-Javier-2 ~ % openssl dgst -md5 -hmac 1234567890abcdef test
HMAC-MD5(test)= d0c9f08ff36829370489c2ddef5e419f
javiergarru@MBP-de-Javier-2 ~ % openssl dgst -md5 -hmac 1234567890abcdef xfile
HMAC-MD5(xfile)= ec52878697fe91feff04753f4982854f
javiergarru@MBP-de-Javier-2 ~ %
```

Question: Does the file size affect the length of HMAC values? Why?

It doesn't affect the length as the HMAC is based on a hash function, in this case md5. As we saw in the previous lab, hash functions map inputs to a fixed-length output space in this case 128 bits. Something that it is important to notice is, that although the size of the output is the same, the time it has taken to compute the second HMAC has been considerably bigger. This is due to the extra computational effort required.

2.3 Practice HMAC with different keys and file contents

Now we are going to try different keys (1,2 and a really long key). We are also going to add a 0 at the end of the extra large file and see how the HMAC changes after encrypting with the same key:

```

javiergarru -- zsh -- 139x15
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha256 -hmac 1 xfile
HMAC-SHA256(xfile)= b5a5e88bbdc85a584bd8473520d48fc7a72d7bc232814e084779acf4d12037a
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha256 -hmac 2 xfile
HMAC-SHA256(xfile)= fd9697acf0f7e9665379e821486795b90fd1954f05447383088391cfbe1ff99f
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha256 -hmac 1234567890-123456789012345678901234567890 xfile
HMAC-SHA256(xfile)= 4a81a962312976af8b87ab6f40b6225a83e021a2afcc507053e2b3a897e2cec8
(base) javiergarru@MBP-de-Javier-2 ~ % tail -c 5 xfile
[?]??
(base) javiergarru@MBP-de-Javier-2 ~ % echo -n "0" >> xfile
(base) javiergarru@MBP-de-Javier-2 ~ % tail -c 5 xfile
[?]??
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha256 -hmac 1 xfile
HMAC-SHA256(xfile)= 6f30a2e0bf6ad2de839f47932da774876c8e5151194b589c1b4b6ace7f2e5626
(base) javiergarru@MBP-de-Javier-2 ~ %

```

As we can see, the different keys significantly change the final HMAC of the file as the Hash functions that are being used have the ability of map close input values to really different output values. We can also see how this occurs when the small change occurs in the file instead of in the key.

Question: Will different keys generate different HMAC values on the same file? Is there any limitation of the length of the key, why?

What can you summarise from this task? Which security property does this feature ensure?

Yes, different keys will generate different HMAC values. We have seen an example of that in the previous screenshot and the reason for this is that they are used to modified the input of the hash functions. There are limitations on the size of the keys as it cannot be longer than the block size of the Hash function in which the HMAC algorithm is based. If the key is longer then most algorithms will automatically hash it, then padded until reaching the block size and use the obtained key. An example is seen here <https://learn.microsoft.com/en-us/dotnet/api/system.security.cryptography.hmacsha256.-ctor?view=net-7.0#:~:text=The%20secret%20key%20for%20HMAC,derive%20a%2032%2Dbyte%20key>. The reason for this is that the padded key is going to be XORed with the ipad and , in another step, with the opad and they need to build a block of the input to the hash.

I can summarise that the small changes in the input generate big inputs in the output which ensures that if the message is tampered during the transaction, computing the HMAC with the correspondent key in the other size of the communication will detect those changes. Integrity will therefore be satisfied. The fact that a small change in the key generates a different HMAC also ensures confidentiality as only the user with the correct key can read the message.

2.4 Try HMAC with different hash algorithms

```

javiergarru -- openssl dgst -md5 -hmac 1 xfile -- 159x10
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha1 -hmac 1 xfile
HMAC-SHA1(xfile)= fdec71fce7a54a1ecfc212eb3e94317a545febf
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha224 -hmac 1 xfile
HMAC-SHA224(xfile)= 6d50fb289ea5f3efc166a2e5a8c7b8bef639db4be28454adfe9f6c5
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha256 -hmac 1 xfile
HMAC-SHA256(xfile)= 6f30a2e0bf6ad2de839f47932da774876c8e5151194b589c1b4b6ace7f2e5626
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -sha512 -hmac 1 xfile
HMAC-SHA512(xfile)= 04941b52f6f65591fba22913a1d8d5a9ef4d3cd927f526204c0b9541a6fb4676932cf03cfb9120df3f524ee29103fc4bec1206061727c6198d876c6889ce5ffa
(base) javiergarru@MBP-de-Javier-2 ~ % openssl dgst -md5 -hmac 1 xfile

```

Question: Why HMAC is compatible with different hash algorithms?

Because the structure of HMAC is independent to the underlying Hash algorithm being used. The only effect this algorithm will have is the block size and output size generated but all these hash functions have the necessary properties to work correctly in the scheme.

2.5 Try CMAC

We will try it with AES-128-cbc and AES-128-ctr:

```
● ● ● javiergarru -- zsh -- 116x17
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -mac CMAC -macopt cipher:AES-128-cbc -macopt hexkey:1234567890123456789012 xfile
CMAC(xfile)= c64aa67df627d4bdf7b810d2f064e955
openssl dgst -mac CMAC -macopt cipher:AES-128-cbc -macopt xfile 8.07s user 0.80s system 98% cpu 9.014 total
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -mac CMAC -macopt cipher:AES-128-ctr -macopt hexkey:1234567890123456789012 xfile
CMAC(xfile)= ea
openssl dgst -mac CMAC -macopt cipher:AES-128-ctr -macopt xfile 66.26s user 1.33s system 99% cpu 1:07.72 total
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -mac CMAC -macopt cipher:AES-128-cbc -macopt hexkey:1234567890123456789 xfile
MAC parameter error "hexkey:1234567890123456789"
8596289024:error:0F076067:common libcrypto routines:OPENSSL_hexstr2buf:odd number of digits:crypto/o_str.c:167:
openssl dgst -mac CMAC -macopt cipher:AES-128-cbc -macopt xfile 0.01s user 0.05s system 58% cpu 0.097 total
(base) javiergarru@MBP-de-Javier-2 ~ %
```

Question: Read the slide of CMAC (page 16) and explain why the last two commands are failed

They failed because the length of the key used was not the correct one. In the case of AES-128-cbc the key must be 128 bit (32 bytes) and the one used in the last execution was less than that. In the case of AES-128-ctr is because the mode uses counters and it is not chained which makes the final output to be different blocks from which we would have to define a specific function to select the length of bits we want to extract. When using CBC is clear that we take the 8 leftmost bits of the final encrypted value.

3 EFFICIENCY TEST

3.1 Compare the time efficiency of HMAC functions with different hash functions

First execution:

```
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -md5 -hmac 1234567890abcdef0 xfile
HMAC-MD5(xfile)= f14d6f823c6a829b5ff9494d9fc846dc
openssl dgst -md5 -hmac 1234567890abcdef0 xfile 9.48s user 0.87s system 94% cpu 10.940 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha1 -hmac 1234567890abcdef0 xfile
HMAC-SHA1(xfile)= 19ee80945fd00ee96d8c0b57563ec2d6c740f60e
openssl dgst -sha1 -hmac 1234567890abcdef0 xfile 7.42s user 1.06s system 95% cpu 8.866 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha256 -hmac 1234567890abcdef0 xfile
HMAC-SHA256(xfile)= 67747789719452382afcb26ff61e6ca9092514e9a2dea9817fb1041c7123a503
openssl dgst -sha256 -hmac 1234567890abcdef0 xfile 13.43s user 0.82s system 99% cpu 14.350 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha512 -hmac 1234567890abcdef0 xfile
HMAC-SHA512(xfile)= eab6f331d61b0e8bafcc077bb83e147477a64014da0fa6c7f1d982cb3dbc930049cecb599f887e8beefaf266d518ce60
388c65f7c54155d380626468602c53b5
openssl dgst -sha512 -hmac 1234567890abcdef0 xfile 8.02s user 0.83s system 98% cpu 8.989 total
(base) javiergarru@MBP-de-Javier-2 ~ %
```

Second execution:

```
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -md5 -hmac 1234567890abcdef0 xfile
HMAC-MD5(xfile)= f14d6f823c6a829b5ff9494d9fc846dc
openssl dgst -md5 -hmac 1234567890abcdef0 xfile 9.57s user 0.93s system 98% cpu 10.610 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha1 -hmac 1234567890abcdef0 xfile
HMAC-SHA1(xfile)= 19ee80945fd00ee96d8c0b57563ec2d6c740f60e
openssl dgst -sha1 -hmac 1234567890abcdef0 xfile 7.44s user 0.85s system 97% cpu 8.525 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha256 -hmac 1234567890abcdef0 xfile
HMAC-SHA256(xfile)= 67747789719452382afcb26ff61e6ca9092514e9a2dea9817fb1041c7123a503
openssl dgst -sha256 -hmac 1234567890abcdef0 xfile 13.44s user 0.94s system 98% cpu 14.548 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha512 -hmac 1234567890abcdef0 xfile
HMAC-SHA512(xfile)= eab6f331d61b0e8bafcc077bb83e147477a64014da0fa6c7f1d982cb3dbc930049cecb599f887e8beefaf266d518ce60
388c65f7c54155d380626468602c53b5
openssl dgst -sha512 -hmac 1234567890abcdef0 xfile 8.02s user 0.82s system 98% cpu 8.960 total
(base) javiergarru@MBP-de-Javier-2 ~ %
```

Third execution:

```
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -md5 -hmac 1234567890abcdef0 xfile
HMAC-MD5(xfile)= f14d6f823c6a829b5ff9494d9fc846dc
openssl dgst -md5 -hmac 1234567890abcdef0 xfile 9.47s user 0.90s system 99% cpu 10.466 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha1 -hmac 1234567890abcdef0 xfile
HMAC-SHA1(xfile)= 19ee80945fd00ee96d8c0b57563ec2d6c740f60e
openssl dgst -sha1 -hmac 1234567890abcdef0 xfile 7.44s user 0.83s system 97% cpu 8.445 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha256 -hmac 1234567890abcdef0 xfile
HMAC-SHA256(xfile)= 67747789719452382afcb26ff61e6ca9092514e9a2dea9817fb1041c7123a503
openssl dgst -sha256 -hmac 1234567890abcdef0 xfile 13.45s user 0.86s system 98% cpu 14.516 total
[(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha512 -hmac 1234567890abcdef0 xfile
HMAC-SHA512(xfile)= eab6f331d61b0e8bafcc077bb83e147477a64014da0fa6c7f1d982cb3dbc930049cecb599f887e8beefaf266d518ce60
388c65f7c54155d380626468602c53b5
openssl dgst -sha512 -hmac 1234567890abcdef0 xfile 8.04s user 0.86s system 98% cpu 9.044 total
(base) javiergarru@MBP-de-Javier-2 ~ %
```

Table:

| HASH function | First run | Second run | Third run | Average |
|---------------|-----------|------------|-----------|---------|
| md5 | 9.48s | 9.57s | 9.47s | 9.51s |
| sha1 | 7.42s | 7.44s | 7.44s | 7.4333s |
| sha256 | 13.43s | 13.44s | 13.45s | 13.44s |
| sha512 | 8.02s | 8.02s | 8.04s | 8.0267s |

Question: How long do these HMAC functions run? Which one is the fastest?

The table shows the answer to both questions. The fastest is the HMAC using hash function sha1. Note that the file had more than 500MB in my case.

3.2 Compare the time efficiency of HMAC functions and corresponding hash functions

Comparing sha512:

```
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha512 -hmac 1234567890 xfile
HMAC-SHA512(xfile)= ada0aec1d2e2c7b4ff9a6b1b0f3d1e6eb03945e050fc3be7430e657e41dfd02dd50557e08e1190d74310e29e2205fc6
b0bb0e1897d9ef730ea3ecdb3abbee4e
openssl dgst -sha512 -hmac 1234567890 xfile 8.01s user 0.80s system 97% cpu 9.009 total
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha512 xfile
SHA512(xfile)= 7b7b8102acc37443bb7d64f78cb9e17de97136bf7529862ff7bfcde551e62d54c33a5f8061668ba4c7ab7c3ffd52b00d596e
94d25a1212bec6861efaf9d4280
openssl dgst -sha512 xfile 8.00s user 0.80s system 98% cpu 8.934 total
(base) javiergarru@MBP-de-Javier-2 ~ %
```

Comparing md5:

```
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -md5 -hmac 1234567890 xfile
HMAC-MD5(xfile)= 1c7861b8fb75bb979e56c07e3ba931bb
openssl dgst -md5 -hmac 1234567890 xfile 9.46s user 0.82s system 99% cpu 10.343 total
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -md5 xfile
MD5(xfile)= 13e8f2707be82c6d7f359de58979c594
openssl dgst -md5 xfile 9.46s user 0.86s system 98% cpu 10.439 total
(base) javiergarru@MBP-de-Javier-2 ~ %
```

Comparing sha1:

```

(javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha1 -hmac 1234567890 xfile
HMAC-SHA1(xfile)= 8ff2d971bf0f97ec24732ec7c2b111256060a176
openssl dgst -sha1 -hmac 1234567890 xfile 7.41s user 0.80s system 98% cpu 8.319 total
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha1 xfile
SHA1(xfile)= 3b7a787f4e756d71f1700e0272187da97f0628c6
openssl dgst -sha1 xfile 7.43s user 0.83s system 98% cpu 8.371 total
(base) javiergarru@MBP-de-Javier-2 ~ %

```

Comparing sha256:

```

(javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha256 -hmac 1234567890 xfile
HMAC-SHA256(xfile)= 3eb246d67f6a7384071b046a13b9a25fa81bd9f64739ffff9c7bcf0cd5d9c02fb
openssl dgst -sha256 -hmac 1234567890 xfile 13.44s user 0.89s system 98% cpu 14.528 total
(base) javiergarru@MBP-de-Javier-2 ~ % time openssl dgst -sha256 xfile
SHA256(xfile)= 7b36b372cb3a0c833bc6c40f34f523d2205245d9852b427e233f41bc51545f7c
openssl dgst -sha256 xfile 13.47s user 0.89s system 99% cpu 14.474 total
(base) javiergarru@MBP-de-Javier-2 ~ %

```

Table:

| HASH function | Hash only | HMAC |
|---------------|-----------|--------|
| md5 | 9.46s | 9.46s |
| sha1 | 7.43s | 7.41s |
| sha256 | 13.44s | 13.47s |
| sha512 | 8.00s | 8.01s |

####

Question: Do the running time of HMAC function and corresponding hash function differ much, why?

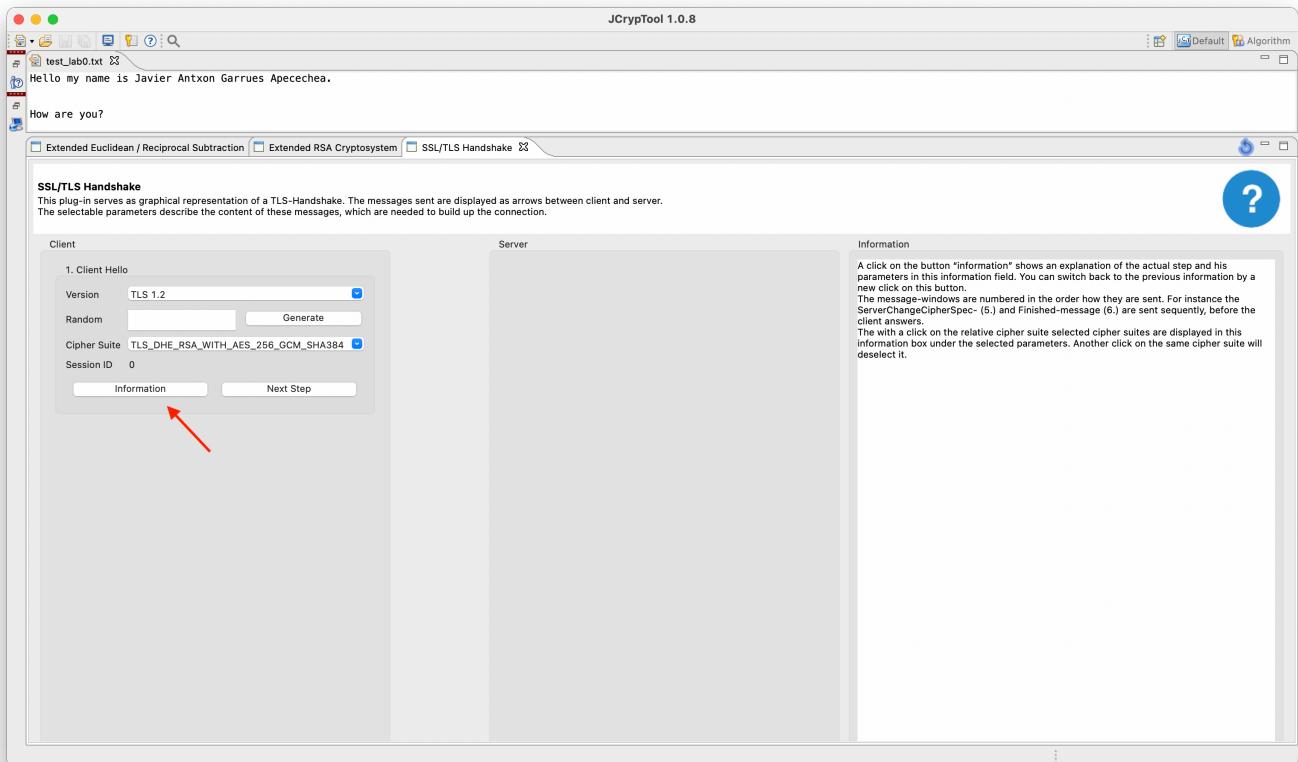

They don't differ much. The reason for this is that the HMAC is implemented in an efficient way such that the hash function is only called once and the rest of operations used in the process are computationally light which means that the time it takes to do them is negligible. Openssl implements different specific modifications that optimize the operations so the time is reduced even more.

Part Two: SSL/TLS Handshake

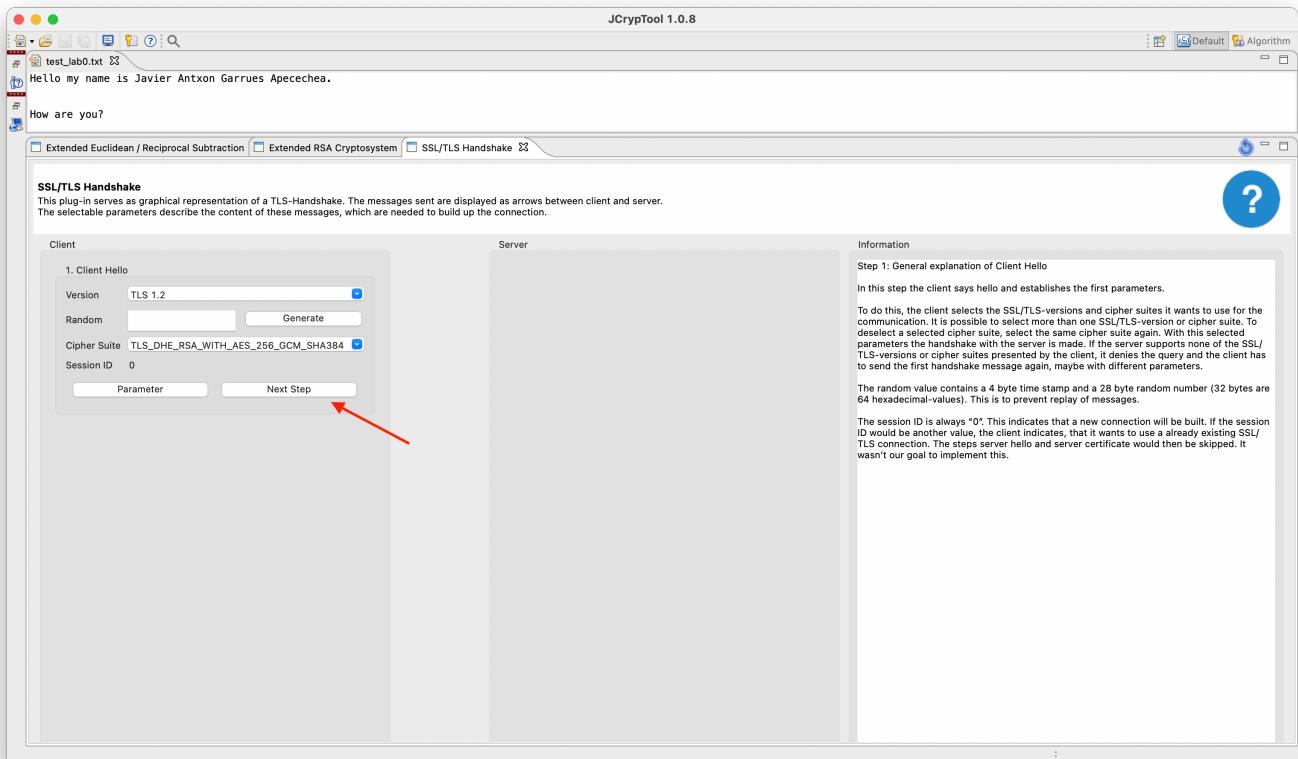

We will use the tool call JCrypTool for the following part of the lab. We are going to select the SSL/TLS handshake option:

- Android Unlock Pattern (AUP)
- Ant Colony Optimization (ACO)
- ARC4 / Spritz
- Certificate Verification
- Chinese Remainder Theorem (CRT)
- Diffie-Hellman Key Exchange (EC)
- Elliptic Curve Calculations
- Extended Euclidean / Reciprocal Subtraction
- Extended RSA Cryptosystem
- Hash Sensitivity
- Homomorphic Encryption (HE)
- Huffman Coding
- Inner States of the Data Encryption Standard (DES)
- Kleptography
- McEliece Cryptosystem
- Merkle Signatures (XMSS^{MT})
- Merkle-Hellman Knapsack Cryptosystem
- Multipartite Key Exchange (BD II)
- Multivariate Cryptography
- Public-Key Infrastructure
- Redactable Signature Schemes (RSS)
- Shamir's Secret Sharing
- Shanks Babystep-Giantstep
- Signature Demonstration
- Signature Verification
- Simple Power Analysis / Square and Multiply
- SPHINCS Signature
- SPHINCS+ Signature
- SSL/TLS Handshake
- Verifiable Secret Sharing
- Winternitz OT-Signature (WOTS / WOTS+)
- Zero-Knowledge: Feige Fiat Shamir
- Zero-Knowledge: Fiat Shamir
- Zero-Knowledge: Graph Isomorphism
- Zero-Knowledge: Magic Door

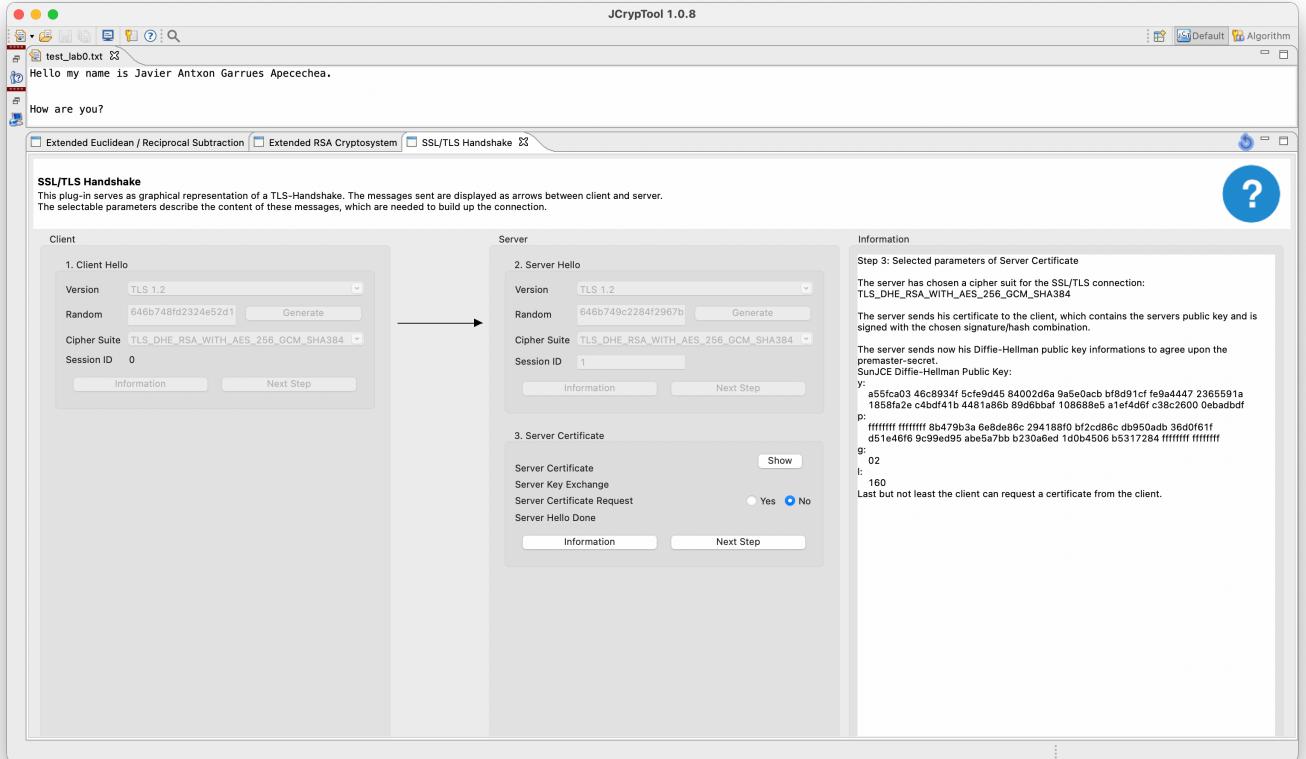

Once there we will see the following window:

We can then click on *Information* and read extra information about the step we are in:

That way we keep going step by step and looking at the information. In the following window we can also click on the *Show* option to see the certificate:

Here we can see what the certificate contains:

Certificate:

The following screenshots show the final steps:

Resetting the process we can come back and select the desired Cipher suite:

Question: Which cipher suite do you prefer? Explain the cipher suite and give your reason choosing the cipher suite.

I would prefer the TLS_DH_RSA_WITH_AES_128_GCM_SHA256. This cipher suite uses Diffie Hellmand key exchange which is less secure than the ECDH but computationally lighter. This would enable to initialize many connections faster from machines with low computational capabilities. RSA will be chosen due to its simplicity and strength for the authentication of the server and generating the public key. I would choose AES instead of DES as I can choose the 128-bit version which is more powerful than the standard DES. This would be used for encryption. The Galois/ Counter Mode uses counters and can be easily parallelized which is something good when doing several operations simultaneously. At last, the underlying hash function is SHA256 instead of SHA384. GCM and SHA will be used to obtain the message tag/digest and ensure data integrity. The choice of SHA256 is based on the fact that it is more widely supported (for now). This would ensure that most times the chosen cipher suite by the client is supported by the server.

Part Three: Summary

In summary, in this lab we have learnt the functioning of HMAC functions and the influence the use of different hash functions have on them. Furthermore we have studied their performance in terms of time and compare the results. At last, we have studied how TLS/SSL handshake protocol works, the different cipher suites available and their meanings.
